1. Abstract

This paper presents a novel mathematical framework, the Universal Rule of Seven (K7 Theory), to explain the spatial distribution of celestial bodies within the Solar System. By deriving a fundamental constant (k) from the Sun-Mercury distance, the model accurately maps the 8 known planets as integer multiples of this unit. Furthermore, the theory predicts a 14-planet orbital resonance model, suggesting the existence of six undiscovered or reclassified major bodies in the Trans-Neptunian region.

2. The Fundamental Constant: The k -Unit

The core of the K7 Theory lies in the septenary division of the primary orbital distance.

Definition: Let D_m be the mean distance from the Sun's center to Mercury's center (0.387 AU).

Formula: $k = \frac{D_m}{7}$

Constant Value: $1k \approx 0.0553 \text{ AU}$.

3. Mathematical Mapping of the Solar System ($n \times k$)

Each planet occupies a specific "Harmonic Point" defined by an integer n .

Planet Mean Distance (AU) Integer Multiple (n) Accuracy

Mercury 0.387 7 Base Unit

Venus 0.723 13 99.8%

Earth 1.000 18 99.5%

Mars 1.524 28 98.4%

Jupiter 5.204 94 99.9%

Saturn 9.582 173 99.8%

Uranus 19.189 347 99.9%

Neptune 30.070 544 99.9%

4. The 14-Planet Resonance & The "Great Jump"

The theory posits that the Solar System is not limited to 8 planets but follows a 14-body resonance.

Pluto's Position: $n = 714$ (102×7).

The Trans-Neptunian Gap: A significant "Jump" occurs after Neptune (544k).

Methodology for Discovery: Future research must utilize $1k$ incremental scanning (715k, 716k, $\dots$) to identify gravitational anomalies and stable orbits beyond 1000k.

5. Conclusion & Earth's Scientific Well-being

The Universal Rule of Seven provides a digital blueprint of cosmic dynamics. By acknowledging these mathematical coordinates, the scientific community can systematically locate the remaining members of our solar family. This model aims to harmonize theoretical physics with observable cosmic resonance.
